POMI

Po-Valley Model Inter-comparison exercise

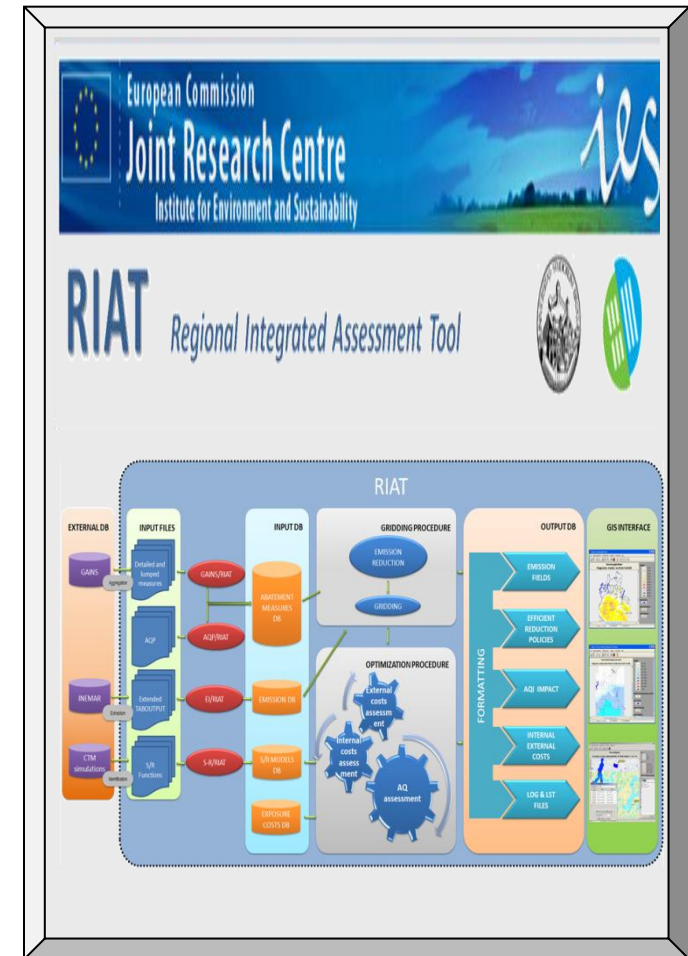

Groups: FUB (D), VITO (B)
INERIS (F), CESI (I),
Met.NO (N), USB (I)

Focus: Yearly O3 and PM levels

Scenarios: BC / Policy / Sensitivity

RIAT

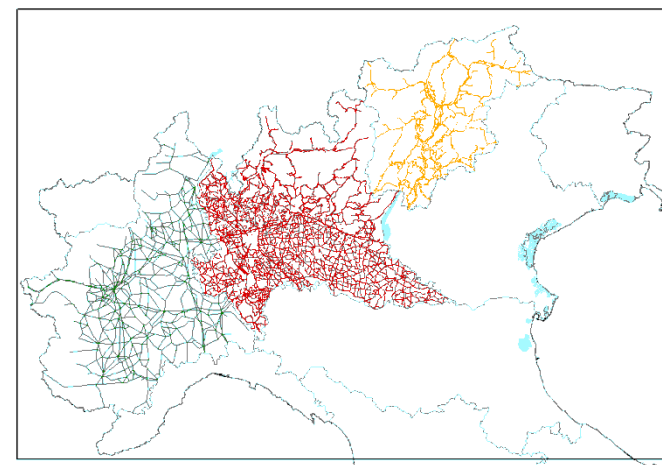

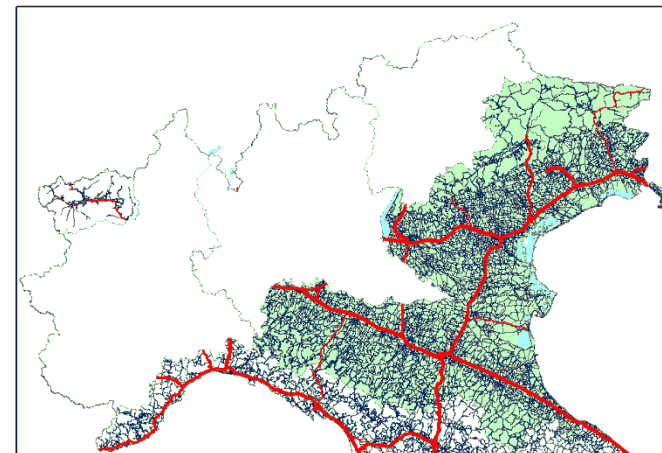

POMI

Objectives:

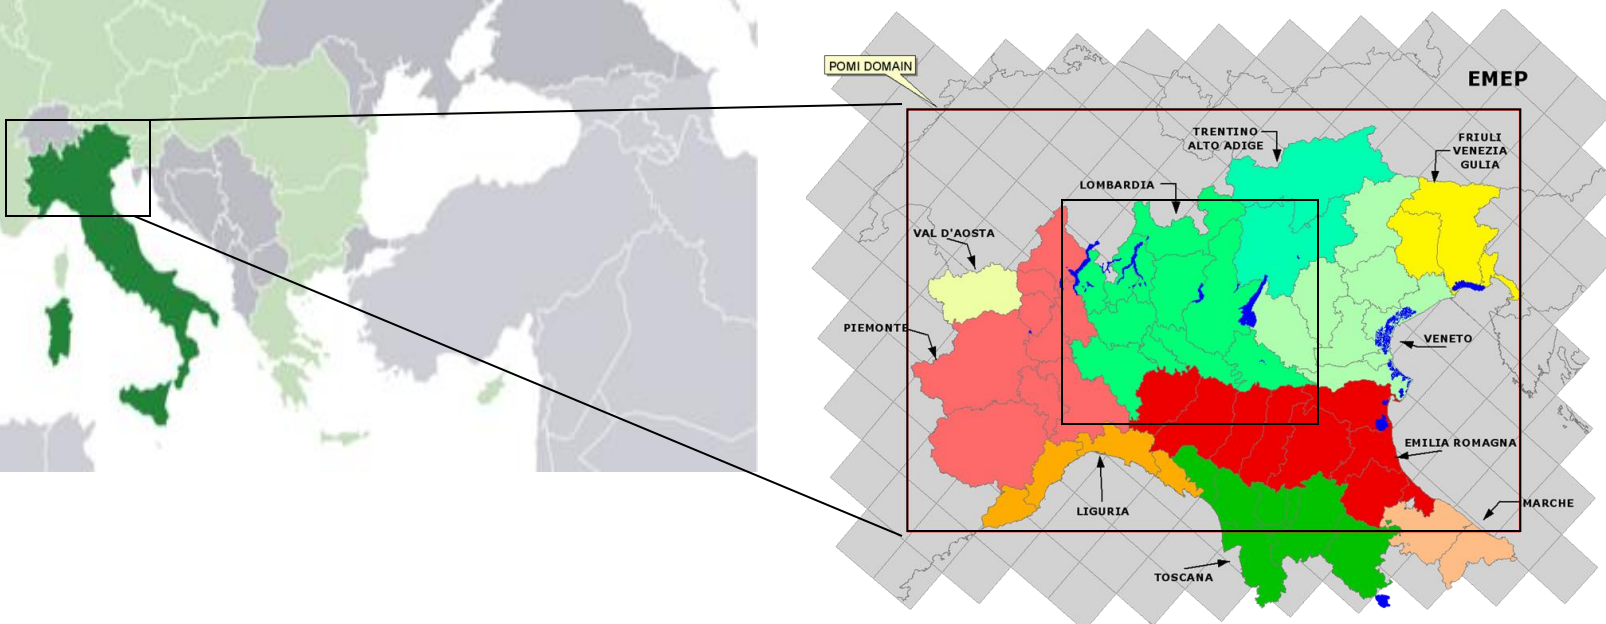

- Analyse the effectiveness of regional emission abatement measures on air quality within the Po-Valley for different time horizons (2010 → 2020). Investigate the added value of regional .vs. European scale measures.
- Assess uncertainties in model responses to emission scenarios (multi-model approach)
- Sensitivity analysis to different factors, e.g. scale, spatial resolution, emissions, boundary conditions, meteorology, ...
- Make use of the most updated information to feed AQ models (construction of an emission inventories covering the entire Po-Valley)

An illustration of the complexity to ensure consistency among different information sources

Base Case 2005

Policy oriented scenarios

(2012 – 2015 – 2020)

- *Current Legislation (CLE)*
- *Maximum Technical Feasible (MTFR)*
- *Air Quality Plan (AQP)*

Sensitivity scenarios

(process understanding)

- *Regional and trans-boundary backgrounds*
- *Boundary conditions*
- *Meteorology*
- *Emission inventory*
- *Specific processes (SOA, biogenics...)*
- *Model configuration*

RIAT scenarios

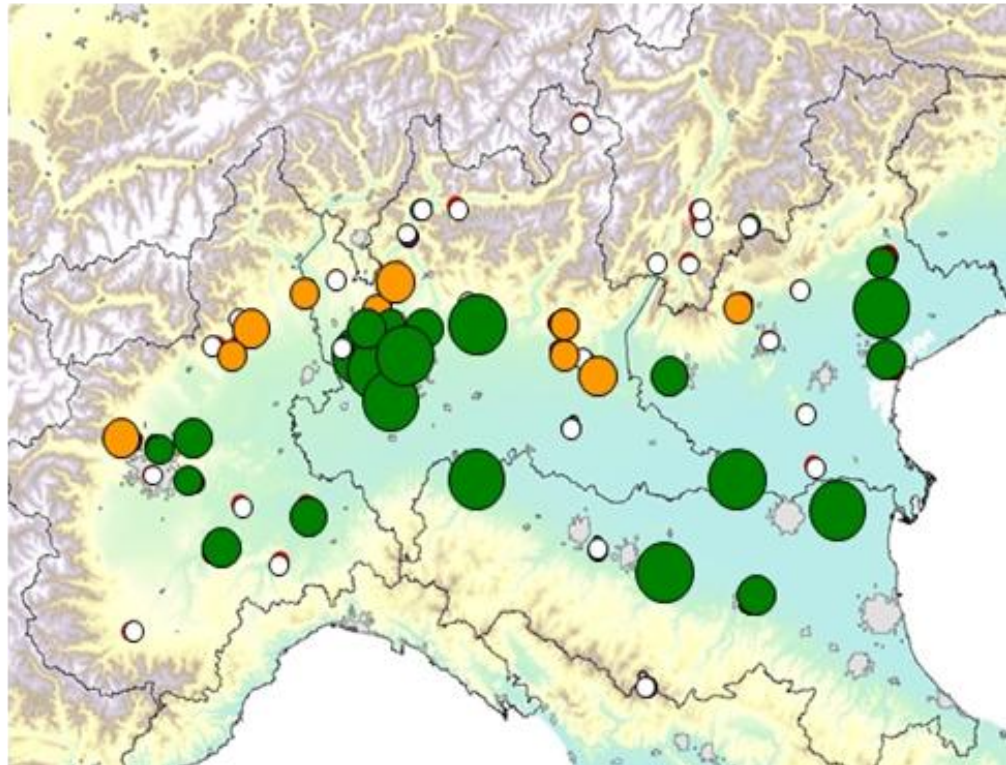

(IAM robustness)

- *Cost effective scenarios*

Despite the improvements made in preparing the emission inventory and developments made in AQ models in the last years, models exhibit difficulties to reproduce accurately AQ fields in the Po Valley area.

- All models show a large variability with O₃ and PM. Some models show satisfactory skills regarding O₃ modelling but almost all models fail to reproduce PM correctly.
- PM concentrations are largely underestimated especially in the wintertime (~40%)
- Model variability is highest (~25 ug/m³) in high concentration areas (i.e. urban areas for PM and pre-Alpine regions for O₃)
- The coarse and organic PM fractions are strongly underestimated especially in winter but speciated measurements are only available at a single station (Ispra)
- Meteorological modeling is a key factor.

Differences in PM₁₀ concentrations (January) obtained with an observation nudged and non nudged meteorological drivers (MM5)

About 80 yearly AQ simulations have been performed in the frame of POMI

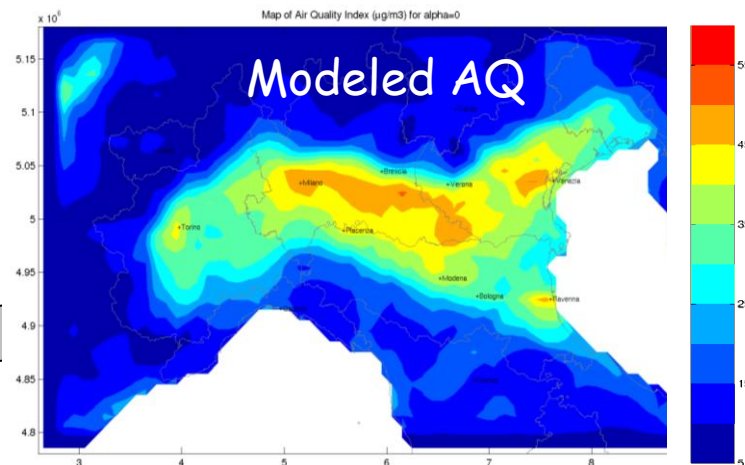

Policy scenarios: CLE, AQP and MFR in 2012, 2015 and 2020)

Sensitivity scenarios (B. Cond., SOA, biogenic, background...)

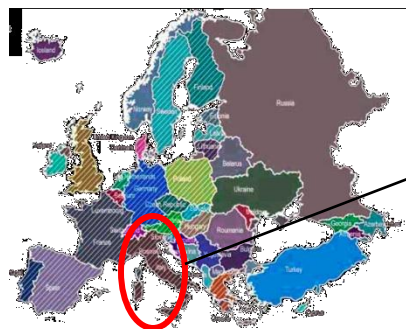

- PM10 levels in RL are mostly a local phenomena (75% from R. Lombardy, 80-85% from Po Valley). With larger percentages in winter time.
- Model responses to emission scenarios are very consistent in relative terms (model bias is corrected)
- More model variability with O3 responses than with PM10
- More consistent responses on mean values than on exceedances

Identification of efficient sub-national and local policies

- Consistent with national and EU air quality standards
- Focused on local/regional scale:
 - specific features of the area
 - the meteorological and chemical regimes of the domain
 - Flexibility in the definition of AQP
- Technological constraints
- Exploration of the optimized solution

PARETO Boundary

Associated Maps:

- ✓ Emissions
- ✓ Air quality
- ✓ Costs

Additional information

- ✓ Reduced emissions & costs per sector
- ✓ Efficiency per technology

- **Although AQ modeling remains a challenge in the Po Valley area, some insight has been gained through the POMI exercise. And the exercise has been a good test case to build confidence in the AQ simulations used in RIAT.**
- **RIAT is one of the few regional IAM existing at present. It makes use of new methodologies (e.g. non-linear ANN), accounts for locally designed measures and via its exploration of the possible optimized solutions provides help to policy makers in their decision taking.**
